**Information Technology – Geographic Information
Framework Data Content Standard
Part 2: Digital orthoimagery**

CAUTION NOTICE

This standard document may be revised or withdrawn at any time. The procedures of the American National Standards Institute require that action be taken periodically to reaffirm, revise, or withdraw this standard. Users of American National Standards may receive current information on all standards by contacting the American National Standards institute (ANSI).

38 **American National Standards Institute**

Information Technology – Geographic Information Framework Data Content Standard
Part 2: Digital orthoimagery

39 **American**
40 **National**
41 **Standard**

66 Approval of an American National Standard requires verification by the
67 American National Standards Institute (ANSI) that the requirements for due
68 process, consensus, and other criteria for approval have been met by the
69 standards developer.
70
71 Consensus is established when, in the judgment of the ANSI Board of
72 Standards review, substantial agreement has been reached by directly and
73 materially affected interests. Substantial agreement means much more than
74 a simple majority, but not necessarily unanimity. Consensus requires that
75 all views and objections be considered, and that a concerted effort be made
76 toward their resolution.
77
78 The use of American National Standards is completely voluntary; their
79 existence does not in any respect preclude anyone, whether he or she has
80 approved the standards or not, from manufacturing, marketing, purchasing,
81 or using products, processes, or procedures not conforming to the standards.
82
83 The American National Standards Institute does not develop standards and
84 will in no circumstances give an interpretation of any American National
85 Standard. Moreover, no person shall have the right or authority to issue an
86 interpretation of an American National Standard in the name of the
87 American National Standards Institute. Request for interpretations should
88 be addressed to the secretariat or sponsor whose name appears on the title
89 page of this standard.

232 **Foreword**

233 Geographic information, also known as geospatial information, both underlies and is the subject
234 of much of the political, economic, environmental, and security activities of the United States. In
235 recognition of this, the United States Office of Management and Budget issued Circular A-16
236 (revised 2002), which established the Federal Geographic Data Committee (FGDC) as a
237 coordinating organization.

238 Work on this standard started under the Geospatial One-Stop e-Government initiative. The
239 standard was developed with the support of the member agencies and organizations of the
240 FGDC and aids in fulfilling a primary objective of the National Spatial Data Infrastructure (NSDI),
241 that is, creation of common geographic base data for seven critical data themes. The seven core
242 data themes are considered framework data of critical importance to the spatial data
243 infrastructure.

244 The increasing need to coordinate collection of new data, identify applicability of existing data,
245 and exchange data at the national level led to the submission of this standard to the ANSI
246 process to become an American National Standard. The national standard contained in this
247 document and its parts was sponsored by Technical Committee L1, Geographic Information
248 Systems, of the InterNational Committee for Information Technology Standards (INCITS), an
249 ANSI-accredited standards development organization.

250 As the Geographic Information Framework Data Content Standard was developed using public
251 funds, the U.S. Government will be free to publish and distribute its contents to the public, as
252 provided through the Freedom of Information Act (FOIA), Part 5 United States Code, Section 552,
253 as amended by Public Law No. 104-231, "Electronic Freedom of Information Act Amendments of
254 1996".

255 **Introduction**

256 The primary purpose of this part of the Geographic Information Framework Data Content
257 Standard is to support the exchange of orthoimagery data. This part seeks to establish a
258 common baseline for the semantic content of orthoimagery databases for public agencies and
259 private enterprises. It also seeks to decrease the costs and simplify the exchange of
260 orthoimagery data among local, Tribal, State, and Federal users and producers. That, in turn,
261 discourages duplicative data collection. Benefits of adopting this part of the standard also include
262 the long-term improvement of the geospatial orthoimagery data within the community.

263 Because of rapidly changing technologies in the geospatial sciences, this part of the Geographic
264 Information Framework Data Content Standard covers a range of specification issues, many in
265 general terms. This part is based on an approved FGDC standard, Content Standards for Digital
266 Orthoimagery, FGDC-STD-008-1999.

267 **Framework Data Content Standard – Digital orthoimagery**

268 **1 Scope, purpose, and application**

269 **1.1 Scope**

270 Digital orthoimagery is one of the basic digital geospatial data framework themes as envisioned
271 by the Federal Geographic Data Committee. This part of the Geographic Information Framework
272 Data Content Standard specifies data content and logical structure for the description and
273 interchange of framework digital orthoimagery. To a certain extent, it also provides guidelines for
274 the acquisition and processing of imagery (leading toward the generation of digital orthoimagery),
275 and specifies the documentation of those acquisition and processing steps. The primary focus of
276 this part is on images sensed in the visible to near infrared portion of the electromagnetic
277 spectrum. However, images captured from other portions of the electromagnetic spectrum are
278 not precluded.

279 **1.2 Purpose**

280 It is the intent of this part of the Framework Data Content Standard to set a common baseline that
281 will ensure the widest utility of digital orthoimagery for the user and producer communities
282 through enhanced data sharing and the reduction of redundant data production. The framework
283 will provide a base on which to collect, register, and integrate digital geospatial information
284 accurately.

285 This part is intended to facilitate the interchange and use of digital orthoimagery data under the
286 framework concept. Because of rapidly changing technologies in the geospatial sciences, this
287 part covers a range of specification issues, many in general terms. This part stresses complete
288 and accurate reporting of information relating to quality control and standards employed in testing
289 orthoimagery data.

290 **1.3 Application**

291 The Digital Orthoimagery part applies to NSDI framework orthoimagery data produced or
292 disseminated by or for the Federal government. According to Executive Order 12906,
293 Coordinating Geographic Data Acquisition and Access: The National Spatial Data Infrastructure,
294 Federal agencies collecting or producing geospatial data, either directly or indirectly (for example,
295 through grants, partnerships, or contracts with other entities), shall ensure, prior to obligating
296 funds for such activities, that data will be collected in a manner that meets all relevant standards
297 adopted through the Federal Geographic Data Committee (FGDC) process.

298 Each thematic part of the Framework Data Content Standard includes a data dictionary based on
299 the conceptual schema presented in that part. To conform to this standard, a thematic dataset
300 shall satisfy the requirements of the data dictionary for that theme. It shall include a value for
301 each mandatory element, and a value for each conditional element for which the condition is true.
302 It may contain values for any optional element. The data type of each value shall be that
303 specified for the element in the data dictionary and the value shall lie within the domain specified
304 for the element.

305 **2 Normative references**

306 Annex A of the Base Document (Part 0) lists normative references applicable to two or more parts
307 of the standard. Informative references applicable only to the Digital Orthoimagery part are listed
308 in Annex D. Annex D of the Base Document lists informative references applicable to two or
309 more of the parts.

310 **3 Standards development**

311 This document is based on an approved FGDC standard, Content Standards for Digital
312 Orthoimagery, FGDC-STD-008-1999, developed initially by the Subcommittee on Base
313 Cartographic Data of the FGDC. The Standards Reference Model, developed by the Standards

Information Technology – Geographic Information Framework Data Content Standard Part 2: Digital orthoimagery

314 Working Group of the FGDC, provides guidance to FGDC subcommittees for the standards
315 development process. The Geographic Information Framework Data Content Standard, Part 2:
316 Digital Orthoimagery has been developed for adoption through the INCITS Technical Committee
317 L1 on Geographic Information Systems, as an American National Standard.

318 **4 Maintenance authority**

319 **4.1 Level of responsibility**

320 The FGDC is the responsible organization for coordinating work on all parts of the Geographic
321 Information Framework Data Content Standard. The U.S. Department of the Interior, United
322 States Geological Survey, National Geospatial Programs Office, working with the FGDC, is
323 directly responsible for development and maintenance of the Geographic Information Framework
324 Data Content Standard, Part 2: Digital Orthoimagery.

325 The FGDC shall be the sole organization responsible for direct coordination with the InterNational
326 Committee for Information Technology Standards (INCITS) concerning any maintenance or any
327 other requirements mandated by INCITS or ANSI.

328 **4.2 Contact information**

329 Address questions concerning this part of the standard to:

330 Federal Geographic Data Committee Secretariat
331 c/o U.S. Geological Survey
332 590 National Center
333 Reston, Virginia 20192 USA

334 Telephone: (703) 648-5514
335 Facsimile: (703) 648-5755
336 Internet (electronic mail): gdc@fgdc.gov
337 WWW Home Page: <http://fgdc.gov>

338 Or

339 Associate Director for Geospatial Information
340 c/o U. S. Geological Survey
341 108 National Center
342 12201 Sunrise Valley Drive
343 Reston, VA, 20192

344 **5 Terms and definitions**

345 Definitions applicable to the Digital Orthoimagery part are listed below. More general terms and
346 definitions can be found in the Base Document (Part 0). Users are advised to consult that part for
347 a complete set of definitions.

348 **5.1** 349 **aerotriangulation**

350 process of using aerial **imagery** or the extension of horizontal and/or vertical control whereby the
351 measurements of angles and/or distances on overlapping **imagery** are related into a spatial
352 solution using the perspective principles of the **imagery** [American Society of Photogrammetry,
353 1980]

354 **5.2** 355 **airborne global positioning system** 356 **AGPS**

357 equipment used to provide initial approximations of exterior orientation, which defines the position
358 and orientation associated with an image as they existed during image capture [Leica
359 Geosystems GIS & Mapping, LLC]

- 360 **5.3**
361 **aliasing**
- 362 effect on a view of a raster file in which smooth curves and other lines become jagged because
363 the resolution of the graphics device or file is not high enough to represent a smooth curve
- 364 **5.4**
365 **band**
- 366 range of wavelengths within the electromagnetic spectrum
- 367 EXAMPLE The near infrared band.
- 368 **5.5**
369 **band interleaved**
- 370 ordered mixing of data from one or more **bands** with corresponding data from other **bands** for the
371 purpose of forming a single image file
- 372 NOTE Images ordered band interleaved by line store values for each band by line sequentially prior to
373 going to the next line and often carry the extension .bil. Images ordered band interleaved by pixels store
374 pixel values for each band before going to the next pixel. They often carry the file extension .bip.
- 375 **5.6**
376 **band sequential**
- 377 sequence of one image **band** followed by another image **band**
- 378 NOTE A band sequential file can be formed by appending bands in sequence within a single file.
- 379 **5.7**
380 **bilinear interpolation**
- 381 mathematical computation for an unknown value based on linear **interpolation** along two axes
- 382 NOTE The axes are derived using a coordinate transformation algorithm to locate the quadrilateral of
383 the four nearest profile points surrounding the unknown point. The interpolation computes the unknown
384 value based on the average, by use of weights and distances, of the four nearest known values.
- 385 **5.8**
386 **color infrared**
387 **false color**
- 388 method for viewing or designating images sensed in the portion of the electro-magnetic spectrum
389 generally from about 0.5 to 1.0 micrometers
- 390 **5.9**
391 **cubic convolution**
- 392 mathematical sampling technique for the interpolation of an unknown value based on a third
393 degree polynomial equation using surrounding known values
- 394 NOTE The image is interpolated from the brightness values of the 16 nearest pixels of the corrected
395 pixel.
- 396 **5.10**
397 **digital image**
- 398 image stored in binary form and divided into a matrix of **pixels**, each consisting of one or more
399 bits of information that represent either the brightness, or brightness and color, of the image at
400 that point
- 401 **5.11**

- 402 **digital number**
403 **brightness number**
404 relative reflectance or emittance of an object in a **digital image**
405 NOTE Digital number is generally referred to as DN.
- 406 **5.12**
407 **digital orthoimage**
408 georeferenced **digital image** or other remotely-sensed data, in which **displacement** of objects in
409 the image due to sensor distortions and orientation, as well as terrain relief, have been removed
- 410 **5.13**
411 **displacement**
412 shift in the position of an image on an image resulting from tilt, scale change, and relief of the
413 area imaged [EM 1110-1-1000]
- 414 **5.14**
415 **georegistration**
416 alignment of one image to another image of the same area by placing any two **pixels** at the same
417 location in both images “in register” resulting in samples at the same point on the Earth
- 418 **5.15**
419 **ground sample distance**
420 **ground sample interval**
421 **ground resolution**
422 **ground pixel resolution**
423 distance on the Earth of the smallest discrete unit of measurement within an orthoimage in the x
424 and y components
- 425 **5.16**
426 **horizontal accuracy**
427 accuracy of horizontal position
- 428 **5.17**
429 **horizontal datum**
430 datum to which horizontal locations of points are referenced
- 431 **5.18**
432 **imagery**
433 visible representation of objects and/or phenomena as sensed or detected by cameras, infrared
434 and multispectral scanners, radar, and photometers [EM 1110-1-1000]
- 435 **5.19**
436 **inertial measurement unit**
437 instrument that records the pitch, roll, and heading of a remote sensing platform
- 438 **5.20**
439 **mosaic**
440 assemblage of overlapping or adjacent photographs or **digital images** whose edges have been
441 matched to form a continuous pictorial representation of a portion of the Earth’s surface
- 442 **5.21**

- 443 **natural color**
- 444 pertaining to a portion of the electro-magnetic spectrum, 0.4 to 0.7 micrometers, that measures
445 blue, green, and red reflectance
- 446 **5.22**
- 447 **orthorectification**
- 448 process of removing geometric errors inherent within photography and **imagery** caused by relief
449 **displacement**, lens distortion, and the like [Leica Geosystems GIS & mapping, LLC]
- 450 **5.23**
- 451 **panchromatic**
- 452 pertaining to monospectral **imagery** that records the intensity of reflected or emitted radiation in
453 the visible spectrum, 0.4 to 0.7 micrometers
- 454 **5.24**
- 455 **pan-sharpening**
- 456 fusing of high-**resolution panchromatic** imagery with lower-**resolution**, multispectral imagery to
457 create a high **resolution** multispectral image
- 458 **5.25**
- 459 **pixel**
- 460 **picture element**
- 461 smallest discrete unit of information found in an image
- 462 NOTE A picture element may have an associated physical metric, size, or interval.
- 463 **5.26**
- 464 **radiometric resolution**
- 465 sensitivity in discriminating between intensity levels
- 466 NOTE Radiometric resolution is inversely related to the number of digital levels used to express the
467 data collected by the sensor. The number of levels is normally expressed as the number of binary digits
468 needed to store the value of the maximum level, for example a radiometric resolution of 1 bit would be 2
469 levels, 2 bit would be 4 levels and 8 bit would be 256 levels. The number of levels is often referred to as the
470 digital number, or DN value. [Association of Geographic information, 1996]
- 471 **5.27**
- 472 **resample**
- 473 derive values for **pixels** by interpolation of surrounding **pixel** values
- 474 **5.28**
- 475 **resolution**
- 476 ability of a sensor to render a sharply defined image
- 477 NOTE Also see, radiometric, spectral, and spatial resolution.
- 478 **5.29**
- 479 **spatial resolution**
- 480 minimum area on the ground that an imaging system, such as a satellite sensor, can distinguish
- 481 **5.30**
- 482 **spectral resolution**
- 483 sensitivity in discriminating between wavelengths

Information Technology – Geographic Information Framework Data Content Standard Part 2: Digital orthoimagery

484 NOTE Spectral resolution measures the total wavelength range of a band in which radiation is
485 measured to produce an image.

486 **5.31** 487 **survey**

488 act or operation of making measurements for determining the relative positions of points on,
489 above, or beneath the Earth's surface [American Society of Photogrammetry, 1980]

490 **5.32** 491 **vertical accuracy**

492 accuracy of elevation

493 **5.33** 494 **void areas**

495 areas in a coverage with no data

496 **6 Symbols, abbreviated terms, and notations**

497 The following symbols, abbreviations, and notations are applicable to the Digital Orthoimagery
498 part. Symbols, abbreviations, and notations applicable to multiple parts are listed in the Base
499 Document (Part 0).

500 AGPS – Airborne Global Positioning System

501 BIL – Band Interleaved by Line

502 BIP – Band Interleaved by Pixel

503 BSQ – Band Sequential

504 CIR – Color Infrared

505 DN – Digital Number

506 DOQQ – Digital Orthophoto Quarter Quadrangle

507 GSD – Ground Sample Distance

508 IMU – Inertial Measurement Unit

509 INS – Inertial Navigation System

510 IPI – Image Processing and Interchange

511 MODIS – Moderate Resolution Imaging Spectroradiometer

512 SDTS – Spatial Data Transfer Standard

513 SPCS – State Plane Coordinate System

514 SPOT – Satellite Pour d'Observation de la Terre

515 TM – Thematic Mapper

516 **7 Data description**

517 Digital orthoimages are georeferenced images of the Earth's surface, collected by a sensor, from
518 which image object displacement has been removed by correcting for sensor distortions and
519 orientation, and for terrain relief. Digital orthoimages encode the optical intensity of sensed
520 radiation in one or more bands of the electromagnetic spectrum as discrete values in an array of
521 georeferenced pixels that model the scene observed. Digital orthoimages have the geometric
522 characteristics of a map. Digital orthoimages are captured from a wide variety of sources and are
523 available in a number of formats, spatial resolutions, and areas of coverage. Many geographic

524 features, including some in other framework data themes, can be interpreted and compiled from
525 an orthoimage.

526 **8 Requirements**

527 **8.1 Digital orthoimagery structure**

528 Framework digital orthoimagery shall consist of images, each of which consists of a two-
529 dimensional, rectangular array of pixels. The ground area covered by each pixel, called ground
530 resolution cells, determines the resolution of each pixel. The pixels shall be arranged in
531 horizontal rows (lines) and vertical columns (samples). The order of the rows shall be from top to
532 bottom; the order of columns shall be from left to right. The uppermost left-hand pixel shall be
533 designated pixel (0,0). Images describing more than 1 band of electromagnetic radiation (natural
534 color, color infrared, multi-band) shall be structured in one of three orders: band interleaved by
535 line (BIL), band interleaved by pixel (BIP), or band sequential (BSQ). The image shall have equal
536 line (row) and column lengths, resulting in a rectangular image. This may be accomplished by
537 padding with over-edge image or non-image pixels, that have a digital number (DN) equal to zero
538 (black or no reflectance), to an edge defined by the extremes of the image. The bounding
539 coordinates of the image shall be documented in accordance with the FGDC Content Standard
540 for Digital Geospatial Metadata. For images that contain over-edge coverage or are padded with
541 non-image pixels, descriptions of both the specific area of interest and any over-edge coverage
542 shall be documented by the metadata. When over-edge information in the image exists, the
543 producer is obliged to describe the image quadrangle in metadata.

544 NOTE Some digital orthoimagery quadrangles include over-edge imagery beyond the boundaries of
545 the area of interest. This part recognizes that annotations may be included in an over-edge image. These
546 images are generally created using color lookup tables that provide for a transparent pixel value to
547 accommodate the portrayal of the over-edge information; otherwise this part limits the orthoimage to the
548 significant pixel values of the image.

549 NOTE Photo enlargements, simply rectified and rubber sheeted images are not orthoimages and do
550 not comply with the basic procedures involved in photogrammetry that produce accurate orthoimages.

551 **8.2 Resolution**

552 When referring to orthoimagery, three different definitions of resolution are important: spatial,
553 spectral, and radiometric.

554 **8.2.1 Spatial resolution**

555 Spatial resolution is the smallest unit which is detected by a sensor [Falkner and Morgan, 2002,
556 p.12]. Often expressed as pixel resolution or ground sample distance (GSD), it defines the area
557 of the ground represented in each pixel in X and Y components. For the purpose of this part,
558 framework digital orthoimages shall have a GSD of 2 meters or finer. Images may be resampled
559 to create coarser resolution images than the original raster data. Subsampling of images may be
560 applied only within the limits defined by the Nyquist theorem [Pratt, 1978]. Images of higher
561 resolution can be used to create orthoimages of less resolution but the reverse is not acceptable.

562 NOTE The Nyquist frequency limits subsampling to a maximum of two times (2X) to avoid undesirable
563 aliasing.

564 **8.2.2 Spectral resolution**

565 Spectral resolution describes a sensor's sensitivity to a particular wavelength band or bands. For
566 the purpose of this part, the focus for framework orthoimage will be on images sensed in the
567 visible to near infrared portion of the electromagnetic spectrum, 0.4 to 1.0 micrometers. However,
568 this does not preclude images captured from other bands.

569 **8.2.3 Radiometric resolution**

570 Radiometric resolution is the sensitivity of a detector to measure radiant flux that is reflected or
571 emitted from a ground object [Falkner and Morgan, 2002, p.12]. Relative radiance from the
572 ground resolution cells shall be described by numerical representations (digital numbers (DNs) or
573 brightness values) of reflected radiance amplitudes. The cell value for a single band shall be
574 recorded as a series of binary digits or bits, with the number of bits per cell determining the
575 radiometric resolution of the image. Where Q is a finite number of bits, the number of discrete
576 DN's shall be given, as follows:

577 $NDN = 2^Q$

578 The DN can be any integer in the range, as follows:

579 $DN_{range} = [0, 2^Q-1]$

580 The radiance values for black and white (gray scale) image data are represented in a single band
581 as 8 to 12-bit data and the radiance values for color images are represented by three bands of 8
582 to 12 bits of binary data per band.

583 EXAMPLE SPOT and TM are both 8 bits per pixel, AVHRR is 10 bits and MODIS is 12 bits per pixel.

584 NOTE Brightness values of most digital orthoimages created are commonly represented as 8-bit binary
585 numbers with a range of values from zero, (black, no reflectance) to 255 (white, full reflectance).

586 **8.3 Areal extent**

587 This part places no constraints on the geographic extent of an orthoimage. Areal extent of
588 quadrilateral orthoimagery may be adjusted as appropriate for the type of sensor and sensor
589 platform, height, requirements of the user, and so on.

590 **8.4 Coordinate systems and reference datums**

591 **8.4.1 Coordinate systems**

592 A common method for referencing coordinate positions on the Earth is essential for integrating
593 geospatial data. While it is desirable that framework data be described by longitude and latitude
594 coordinates, orthoimagery is more often represented in a grid coordinate system, such as
595 Universal Transverse Mercator (UTM) or State Plane Coordinate Systems (SPCS).

596 **8.4.2 Reference datums**

597 The North American Datum of 1983 (NAD83) or World Geodetic System 1984 (WGS84) datum
598 shall be used as the horizontal datum for framework digital orthoimagery.

599 **8.4.3 Georegistration**

600 All orthoimages shall be georeferenced to reflect their correct locations, both horizontally and
601 vertically. Georegistration will be described by a 4-tuple in the metadata which will establish the
602 geographical position of the first pixel in the first row of the image [pixel (0,0)]. The metadata will
603 reflect the row # = 0, column # = 0, and georeference values in X and Y for the documented
604 datum and horizontal coordinate system. Under this part, georegistration (spatial coordinates)
605 refers to the center of the pixel. This establishes the georegistration at one point in the
606 orthoimage. Since row and column offsets are both constant and supplied by the metadata,
607 (XY_pixel resolution), all other points can be georegistered. Additional 4-tuples may be provided
608 for additional georegistration.

609 NOTE Photo enlargements, simply rectified and rubber sheeted images are not orthoimages and do
610 not comply with the basic procedures involved in photogrammetry that produce accurate orthoimages.

611 **8.5 Accuracy requirements**

612 This part specifies that map accuracy shall be determined by comparing the mapped location of
613 selected well defined points to their "true" location, as determined by a more accurate,

Information Technology – Geographic Information Framework Data Content Standard Part 2: Digital orthoimagery

614 independent field survey. Accuracy of new or revised spatial data shall be reported according to
615 the National Standard for Spatial Data Accuracy (NSSDA) [FGDC-STD-007.3-1998]. Accuracy of
616 existing or legacy spatial data and maps may be reported, as specified, according to the NSSDA
617 or the accuracy standard by which they were evaluated.

618 Framework digital orthoimagery accuracy shall employ the NSSDA, which implements a
619 statistical and testing methodology for estimating the positional accuracy of points in digital
620 geospatial data, with respect to georeferenced ground positions of higher accuracy. This
621 reporting methodology provides a common language for reporting positional accuracy so that
622 users can evaluate datasets for fitness of use for their applications. The NSSDA uses root-mean-
623 square error (RMSE) to estimate positional accuracy. Accuracy is reported in ground distances
624 at the 95% confidence level. Accuracy reported at the 95% confidence level means that 95% of
625 the positions in the dataset will have an error with respect to true ground position that is equal to
626 or smaller than the reported accuracy value. The reported accuracy value reflects all
627 uncertainties, including those introduced by geodetic control coordinates, compilation, and final
628 computation of ground coordinate values in the product. The NSSDA does not define threshold
629 accuracy values. Users are encouraged to establish thresholds for their product specifications
630 and applications and for contracting purposes. Data producers may elect to use accuracy
631 thresholds in standards such as the National Map Accuracy Standards of 1947 [U.S. Bureau of
632 the Budget, 1947] or Accuracy Standards for Large-Scale Maps [American Society for
633 Photogrammetry and Remote Sensing (ASPRS) Specifications and Standards Committee, 1990]
634 if they decide that these values are applicable to their digital geospatial data accuracy
635 requirements. However, accuracy of new or revised data products will be reported according to
636 the NSSDA. Data producers shall ensure that all critical components have known accuracies
637 suitable for the construction of orthoimagery, and that those accuracies are reported in the
638 metadata. Producers of digital orthoimagery must report the horizontal positional accuracy of
639 data.

640 **8.5.1 Tested orthoimages RMSE**

641 Per NSSDA, report accuracy at the 95% confidence level for data tested for both horizontal and
642 vertical accuracy as:

643 Tested ____ (meters, feet) horizontal accuracy at 95% confidence level

644 ____ (meters, feet) vertical accuracy at 95% confidence level

645 **8.5.2 Untested orthoimages RMSE**

646 Per NSSDA, report accuracy at the 95% confidence level for data produced according to
647 procedures that have been demonstrated to produce data with particular horizontal and vertical
648 accuracy values as:

649 Compiled to meet ____ (meters, feet) horizontal accuracy at 95% confidence level

650 ____ (meters, feet) vertical accuracy at 95% confidence level

651 **8.5.3 Horizontal positional accuracy narrative**

652 Enter the text “National Standard for Spatial Data Accuracy” for these metadata elements, as
653 appropriate to dataset spatial characteristics.

654 **8.5.4 Horizontal positional accuracy reporting**

655 Regardless of whether the data was tested by an independent source of higher accuracy or
656 evaluated for accuracy by alternative means, provide a complete description on how the values
657 were determined in metadata, as appropriate to dataset spatial characteristics.

658 **8.6 Production components**

659 The following section describes requirements for the primary production components of digital
660 orthoimages: image sources, elevation data, control, and camera or sensor calibration data. It
661 follows then that all orthoimagery discussed will be created through a true displacement

662 rectification process. Georeferenced or “rubber-sheeted” images, therefore, are not acceptable
663 as true orthoimages.

664 **8.6.1 Image sources**

665 Source for digital orthoimages may be from any remote sensing device capable of producing
666 images with resolutions 2-meters or finer. Remote sensing devices may be photographic or
667 electronic, airborne or satellite.

668 **8.6.1.1 Aerial camera images**

669 Continuous tone images in the visible light portion of the electromagnetic spectrum from aerial
670 cameras are the primary source currently used to produce digital orthoimages. Sensor types for
671 orthoimages compliant with this part shall be confined to black and white (panchromatic), color
672 infrared (CIR), and natural color. Black and white orthoimages may be generated from CIR and
673 natural color source.

674 **8.6.1.2 Aerial photo image scanning**

675 A digital image may be created from an analog photographic image utilizing a high-resolution
676 scanner. The intent of the scanning process is to capture the same level of detail in the digital
677 image as is found on the film. The combination of the scanner optical resolution setting and the
678 scale of the source imagery will determine the ground resolution distance that can be attained
679 from the digital image following orthorectification. The optical resolution of the scanning process is
680 typically measured in either micrometers or dots-per-inch and should as closely as possible
681 match the intended ground sample distance (GSD) without excessive resampling. Resampling
682 from a higher resolution to create a lower resolution image is acceptable.

683 **8.6.1.3 Digital images**

684 Images from airborne and satellite platforms, utilizing digital cameras or scanners, are
685 increasingly more common sources used in the production of digital orthoimages. For the
686 purposes of framework orthoimagery they include images from electro-optical, near infrared, and
687 multi-spectral operating in the visible to near (reflected) infrared wavelengths, 0.4 to 1.0
688 micrometers. This document does not discuss the details and specifications of digital cameras or
689 satellite remote sensors. Nor does it debate the advantages or disadvantages of using one
690 image acquisition system over another.

691 **8.6.2 Elevation data**

692 Elevation data used to correct displacement shall be sufficiently accurate to ensure the image
693 meets user defined requirements for the intended accuracy: the appropriate point density, point
694 spacing, and area coverage in order to meet the accuracy requirements and scale of the
695 orthoimage, and to reliably describe the terrain.

696 Note For more information on elevation data refer to Geographic Information Framework Data
697 Content Standard, Part 3: Elevation.

698 **8.6.3 Calibration data**

699 With the exception of documenting the appropriate source metadata, camera or imaging
700 instrument calibration parameters requirements for production purposes are not covered by this
701 part.

702 Note Information on analog camera calibration can be found in the USGS publication, Aerial Camera
703 Specifications (revised January 2003).

704 **8.6.4 Control data**

705 Control point locations are required when creating digital orthoimagery. Without control
706 information, rigorous orthorectification is not possible. For orthorectification, control must have
707 known X, Y, and Z-coordinate values. The process of orthorectifying the image must use a 3-
708 dimensional (3D) space resection algorithm. Images processed via simple rectification or rubber-

709 sheeting are not considered true orthoimages: they are not true orthogonal images from which
710 accurate measurements may be ascertained. The accuracy of the control determines the initial
711 accuracy of the orthoimage. Control must be used to provide the 3D foundation during the
712 orthorectification process and can be acquired from a variety of sources.

713 NOTE More detailed information is contained in Annex C.

714 **9 Image rectification and restoration**

715 Image rectification and restoration are processes for correcting distortions and degradations that
716 result from image acquisition or production. Digital orthoimagery is processed in a number of
717 ways, and different orthoimagery production systems have unique characteristics. However, all
718 accept raw (or unprocessed) imagery that contain some degree of error in geometry (geometric
719 distortion) and in the measured brightness values of the pixels (radiometric distortion). This part
720 specifies rectification or restoration procedures only in context of geometric and radiometric
721 corrections.

722 **9.1 Geometric correction**

723 All systematic and random errors shall be removed to the extent required to meet orthoimagery
724 accuracy requirements as defined by the intended user. Nearest neighbor, bilinear interpolation,
725 and cubic convolution resampling algorithms are common methods used to transform image
726 values to fit map geometry. Nearest neighbor resampling is not recommended for the large-scale
727 framework because of the disjointed appearance in the output due to spatial offsets as great as
728 one-half pixel. Images transformed using bilinear interpolations are generally acceptable. A
729 precise resampling method such as cubic convolution is recommended.

730 Note Geometric corrections are performed to match raw image data to map geometry. Distortions
731 can be classified as either systematic (predictable errors that follow some definite mathematical or physical
732 law or pattern associated with particular processes and instruments) or random (errors that are wholly due to
733 chance and do not recur). Most of the distortions associated with orthoimagery are random. Terrain relief,
734 random variation in platform position, and faulty elevation data are the sources of nonsystematic distortion,
735 or random errors. These random errors can be detected by comparing identifiable points on an image to
736 their known ground coordinates.

737 **9.1.1 Image smear**

738 When image smears occur, efforts shall be made to correct them or to identify them as
739 anomalies. Where feasible, areas of image smear may spatially be defined as polygons, linked to
740 documentation in lineage metadata.

741 Note Occasionally, because of spikes in the elevation data or excessive topographic relief, an
742 anomaly or artifact best described as an "image smear" may appear on a rectified image. Basically, the
743 steepness of the terrain is such that some ground image is effectively hidden from view (for example, on the
744 backside of the mountain or the sides of a steep cliff). This can be especially prominent near the edge of
745 images from large-scale aerial photography (generally, incidence of the anomaly decreases as the altitude
746 of the sensor platform increases). When that portion of the scanned raster image is adjusted to its
747 conjugate area on the elevation model, the void area in the image is assigned brightness values via an
748 interpolation algorithm that uses the visible image surrounding the void. This sometimes results in a
749 "smeared" or "stretched" area on the image.

750 **9.1.2 Other elevation – related geometric distortions**

751 Double or missing features in the image may be indications of a poor elevation model or
752 unsuitable control. Such distortions may render the image unusable. Producers should recheck
753 the source elevation or control to establish if the distortion is systematic or not; if the distortion is
754 systematic, a better elevation model and (or) control should be used. Non-systematic distortions
755 need to be reviewed on a case-by-case basis and if deemed acceptable by the producer and
756 customer, identified and recorded in the metadata by the producer.

Information Technology – Geographic Information Framework Data Content Standard Part 2: Digital orthoimagery

757 NOTE Linear features (such as highways and bridges) may require special treatment to maintain their
758 alignment, form, and integrity.

759 **9.2 Radiometric correction**

760 Image brightness values may deviate from the brightness values of the original imagery, due to
761 image value interpolation during the scanning, rectification, and post-processing procedures and
762 it is common practice to perform some radiometric enhancements and corrections (for example,
763 contrast stretching, analog dodging, noise filtering, destriping, edge matching) to images prior to
764 release of the data. However, data producers are cautioned to minimize the amount of
765 radiometric correction applied to an image. Data producers shall use processing techniques that
766 minimize data loss from the time the information was captured until its release to the users.

767 **9.3 Data completeness**

768 Visual verification shall be performed for image completeness, to ensure that, whenever possible,
769 no gaps exist in the image area.

770 **9.4 Cloud cover**

771 Any cloud cover or cloud shadows which obscure image features may render the image
772 unusable. However, for some areas of an image (for example, over broad bodies of water) cloud
773 cover obstruction may be deemed acceptable to some users. Therefore, some users may find
774 images containing varying percentages of cloud cover or cloud shadow to be acceptable.

775 **10 Image mosaicking**

776 Single orthoimages are commonly created through the mosaicking of multiple images and many
777 producers go through extensive image processing steps to attain a “seamless” appearance. This
778 document will not discuss mosaic procedures nor will it prescribe the degree of quality for the
779 appearance of mosaicked orthoimages. However, all the images that comprise the source of a
780 mosaicked image shall be documented in the metadata field.

781 **11 Data transfer formats**

782 Data transfer formats for digital orthoimagery are not specified in this part. Data producers are
783 encouraged to employ ISO and ANSI standards for information exchange. In all cases,
784 producers shall provide detailed descriptions of the format.

785 **12 Metadata**

786 The FGDC emphasizes the importance of good metadata to support the exchange and use of
787 geospatial data: providing quality information will allow users to match data to their needs. Well-
788 crafted metadata facilitates the search and collection process while alleviating some of the
789 burden on the user to assess quality and applicability of data. The more metadata there is for a
790 product, the more it can support the user’s determination of its reliability, quality, and accuracy.
791 Metadata is intended to be of value to the producer as well as to the user.

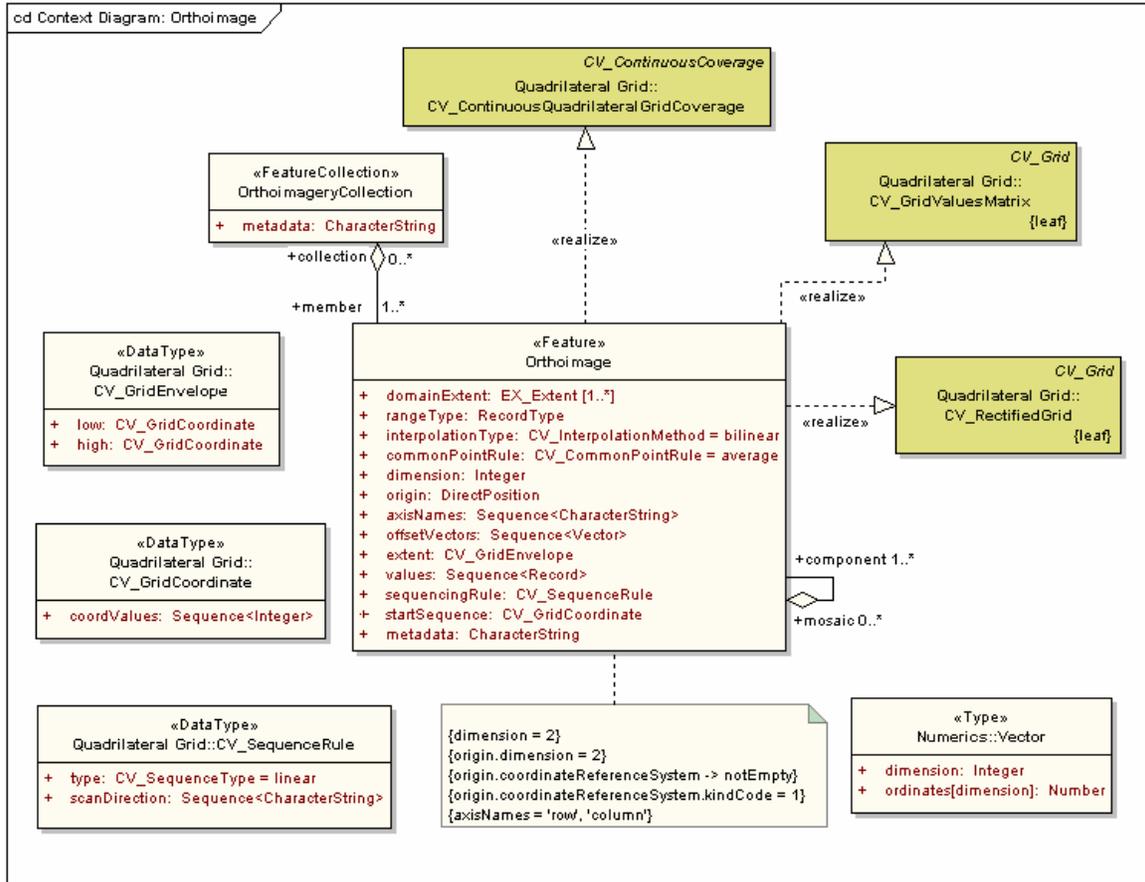

792 The FGDC Content Standard for Digital Geospatial Metadata [FGDC-STD-001-1998] with all
793 FGDC-approved profiles of and extensions to it, in conjunction with ISO 19115, are the source for
794 terminology and definitions relating to metadata. Executive Order 12906, Coordinating
795 Geographic Data Acquisition and Access: The National Spatial Data Infrastructure, requires all
796 Federal agencies to use FGDC-STD-001-1998 to document data that they produce beginning in
797 1995.

Annex A (normative) Orthoimagery UML model

A.1 Orthoimagery schema

801
802

803
804
805

Figure A.1 – Orthoimagery

A.1.1 Classes of the schema

807 The orthoimagery schema specified in this annex includes two classes: Orthoimage, which is a
808 realization of three types specified in ISO 19123, and OrthoimageryCollection.

A.1.2 Orthoimage

A.1.2.1 Introduction

811 The class Orthoimage (Figure A.1) realizes three types specified in ISO 19123:
812 CV_ContinuousQuadrilateralGridCoverage, CV_GridValuesMatrix, and CV_RectifiedGrid. It
813 implements 13 attributes specified for those types in ISO 19123, as well as one attribute and one
814 association specified in this part. Its attributes use classes specified in ISO standards as data
815 types.

816 **A.1.2.2 Attribute: domainExtent**

817 The attribute *domainExtent* shall describe the extent of the domain of the orthoimagery coverage.
818 It uses the data type EX_Extent specified in ISO 19115. EX_Extent has several subtypes
819 including EX_GeographicBoundingBox, EX_BoundingPolygon, EX_GeographicDescription,
820 EX_TemporalExtent, EX_SpatioTemporalExtent, and EX_VerticalExtent. This part requires that
821 the attribute be populated with a value for at least one of these subtypes.

822 **A.1.2.3 Attribute: rangeType**

823 The attribute *rangeType* shall provide a description of the attributes in the range of the coverage.
824 The class RecordType is specified in ISO 19103. An instance of RecordType consists of a set of
825 keyword:value pairs in which the keyword is an attribute name and the value is the data type of
826 the attribute.

827 **A.1.2.4 Attribute: interpolationType**

828 The attribute *interpolationType* shall identify the interpolation method recommended for
829 evaluating the coverage. The code list CV_InterpolationMethod is specified in ISO 19123.

830 **A.1.2.5 Attribute: commonPointRule**

831 The attribute *commonPointRule* shall identify a rule to be followed in evaluating a coverage if the
832 position at which evaluation is to be done falls within or on the boundary between two or more
833 domain objects. In the case of a grid coverage, it applies only if the position falls on a grid line.
834 The code list CV-CommonPointRule is specified in ISO 19123.

835 **A.1.2.6 Attribute: dimension**

836 The attribute *dimension* shall identify the dimension of the grid. In the case of orthoimagery, the
837 grid dimension is always 2 as indicated by the constraint {dimension = 2}.

838 **A.1.2.7 Attribute: origin**

839 The attribute *origin* shall identify the position of the origin of the grid coordinate system with
840 respect to an external coordinate reference system. The data type DirectPosition (A.1.8) is
841 specified in ISO 19107. The constraint {origin.dimension = 2} indicates that the DirectPosition
842 shall be described by a 2D coordinateDirectPosition that has an optional association to the class
843 SC_CRS (A.1.9) specified in ISO 19111. That association is mandatory for this part, as indicated
844 by the constraint: {origin.coordinateReferenceSystem -> notEmpty}.

845 This part also specifies that the external coordinate reference system shall use either the North
846 American Datum of 1983 (NAD83) or the datum defined for the World Geodetic System of 1984
847 (WGS84).

848 **A.1.2.8 Attribute: axisNames**

849 The attribute *axisNames* shall provide a list of the names of the grid axes. The length of the list
850 equals the value of the attribute *dimension*. This part requires the axis names to be “row” and
851 “column” as indicated by the constraint {axisNames = “row”, “column”}.

852 **A.1.2.9 Attribute: offsetVectors**

853 The attribute *offsetVectors* shall describe the orientation of the grid axes with respect to the
854 external coordinate reference system as well as the spacing between grid lines. Its value is a
855 Sequence of Vectors. The data type Vector (0) is specified in ISO/TS 19103. The length of the
856 sequence shall equal the value of the attribute *dimension*. ISO 19123 specifies that the ordering
857 of the sequence of *offsetVectors* shall be the same as the ordering of the sequence of
858 *axisNames*.

859 **A.1.2.10 Attribute: extent**

860 The attribute *extent* shall identify the set of grid points for which attribute values are provided.
861 The data type CV_GridEnvelope (A.1.4) is specified in ISO 19123.

862 **A.1.2.11 Attribute: values**

863 The attribute *values* shall provide a sequence containing all of the values associated with grid
864 points within the extent of the coverage. Each record in the sequence shall contain the list of
865 values for a single grid point. The data type Record is specified in ISO 19103. For this attribute,
866 each Record shall conform to the RecordType provided as the value for Orthoimage.rangeType.

867 **A.1.2.12 Attribute: startSequence**

868 The attribute *startSequence* shall identify the grid coordinates of the point associated with the first
869 record in the sequence of *values*. The data type CV_GridCoordinate (A.1.5) is specified in ISO
870 19123.

871 **A.1.2.13 Attribute: sequencingRule**

872 The attribute *sequencingRule* shall identify the rule to be followed in assigning records from the
873 sequence of *values* to individual grid points. The data type CV_SequenceRule (A.1.6) is
874 specified in ISO 19123.

875 **A.1.2.14 Attribute: metadata**

876 The attribute *metadata* shall provide a link to metadata about the Orthoimage.

877 **A.1.2.15 Association: Aggregation**

878 The optional association Aggregation may link an instance of Orthoimage to other instances in
879 two ways. The role name *collection* identifies an OrthoimageryCollection to which the
880 Orthoimage belongs. In the role of *mosaic*, an instance of Orthoimage is characterized as an
881 aggregate of one or more other instances of Orthoimage. In the role of *component*, an instance
882 of Orthoimage is characterized as a member of one or more *mosaics*.

883 **A.1.3 OrthoimageryCollection**

884 **A.1.3.1 Introduction**

885 The class OrthoimageryCollection represents a set of Orthoimages that are transferred as a set.

886 **A.1.3.2 Attribute : metadata**

887 The attribute *metadata* shall provide a link to metadata about the OrthoimageryCollection.

888 **A.1.3.3 Associated role name: member**

889 The role name *member* identifies an Orthoimage that belongs to the OrthoimageryCollection.

890 **A.1.4 CV_GridEnvelope**

891 **A.1.4.1 Introduction**

892 The data type class CV_GridEnvelope has two attributes.

893 **A.1.4.2 Attribute: low**

894 The attribute *low* takes as its value an instance of CV_GridCoordinate that contains the minimum
895 coordinate of the grid envelope with respect to each axis of the grid.

896 **A.1.4.3 Attribute: high**

897 The attribute *high* takes as its value an instance of CV_GridCoordinate that contains the
898 maximum coordinate of the grid envelope with respect to each axis of the grid.

899 **A.1.5 CV_GridCoordinate**

900 **A.1.5.1 Introduction**

901 The data type class CV_GridCoordinate has a single attribute.

902 **A.1.5.2 Attribute: coordValues**

903 The attribute *coordValues* contains the coordinates of a grid point expressed as integer values.

904 **A.1.6 CV_SequenceRule**

905 **A.1.6.1 Introduction**

906 The data typeclass *CV_SequenceRule* describes the method to be followed in assigning records
907 from the sequence of *Orthoimage.values* to grid points within the grid envelope. It has two
908 attributes.

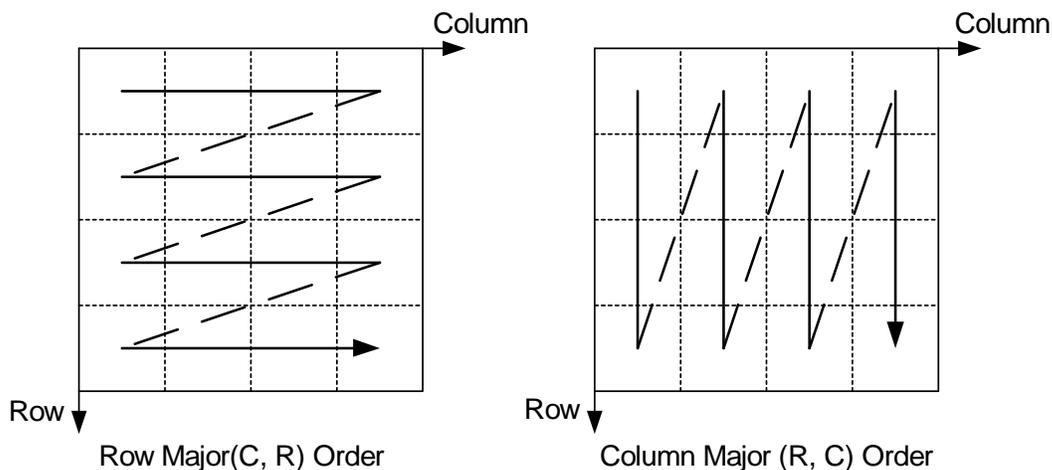

909 **A.1.6.2 Attribute: type**

910 The attribute *type* identifies the sequencing method to be used. The data type
911 *CV_SequenceType* is specified in ISO 19123. The default value is "linear". Other methods for
912 sequential enumeration are described in Annex D of ISO 19123.

913 **A.1.6.3 Attribute: scanDirection**

914 The attribute *scanDirection* is a sequence of signed axis names that indicates the direction in
915 which sequencing operates. An additional element may be included in the sequence to describe
916 interleaving of attribute values. In the case of linear scanning of a 2D grid, grid coordinates are
917 incremented first along a grid line parallel to the first axis named in the list, and then along the
918 second axis. To describe interleaving, the range of the coverage is treated similarly to a grid axis
919 – the index of the list of values in a record is incremented in the same way that the grid
920 coordinates are incremented.

921 **EXAMPLE 1** In Figure A.2, the grid axes are named Row (R) and Column (C). The grid origin is at the
922 upper left corner, and the axes are positive downward and to the right.

923

924 **Figure A.2 – Examples of scan directions**

925

926 **EXAMPLE 2** Given grid axes named Row (R) and Column (C), and identifying the range of the grid
927 coverage as A, the various forms of interleaving are identified by ordering the axes as shown in the table
928 below.

929

Table A.1 – Examples of interleaving

Organization	Axis Sequence
Band interleaved by pixel	ACR or ARC
Band interleaved by row	CAR
Band interleaved by column	RAC
Band sequential	CRA or RCA

930

931 **A.1.7 Vector**

932 **A.1.7.1 Introduction**

933 The type class Vector is specified in ISO 19103. It has two attributes.

934 **A.1.7.2 Attribute: dimension**

935 The attribute *dimension* indicates the dimension of the coordinate reference system, which is
936 constrained to 2 in the case of this part.

937 **A.1.7.3 Attribute: ordinates**

938 The attribute *ordinates* provides the ordinates relative to each axis of the coordinate reference
939 system.

940 **A.1.8 DirectPosition**

941

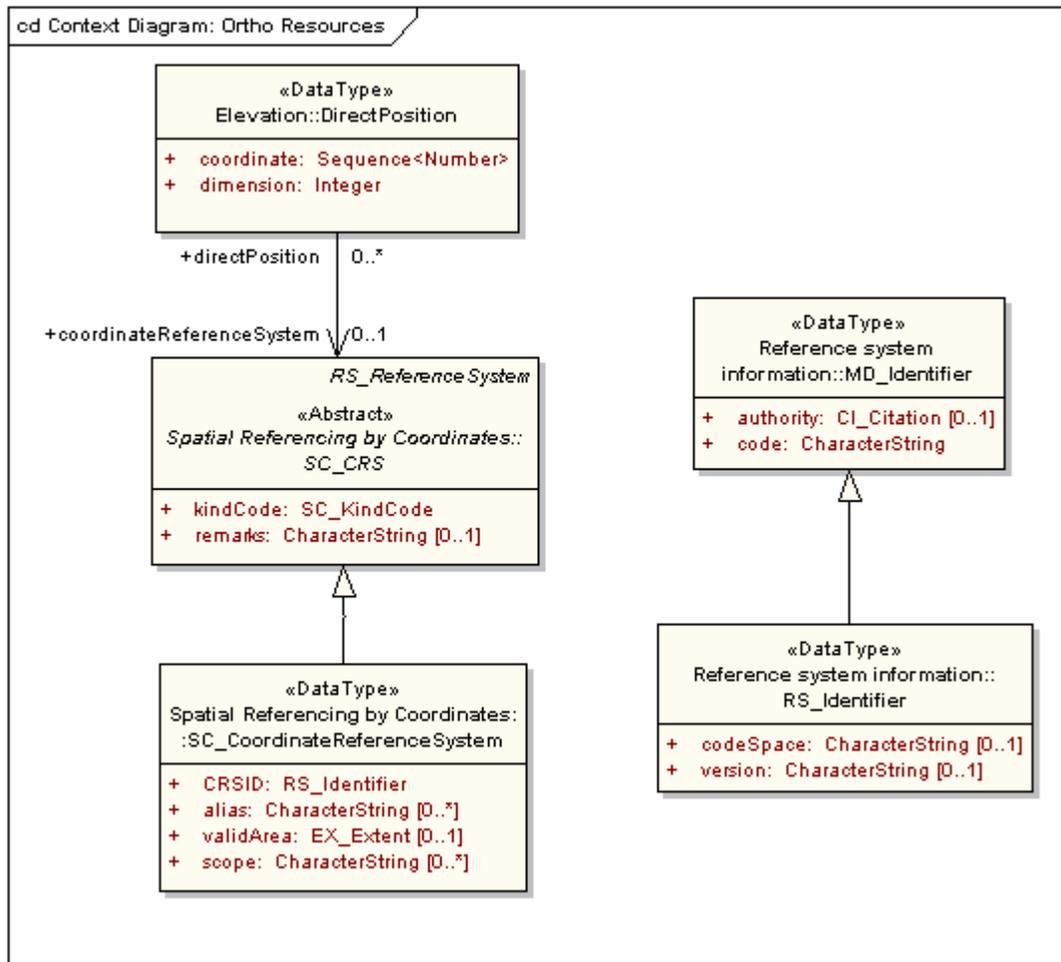

Figure A.3 – DirectPosition

942

943

944

945 **A.1.8.1 Introduction**

946 The data type class DirectPosition (Figure A.3) is specified in ISO 19107. DirectPosition has two
947 attributes that carry the coordinates of a position and the coordinate dimension. It also has an
948 optional association to the class SC_CRS specified in ISO 19111.

949 **A.1.8.2 Attribute: coordinate**

950 The attribute *coordinate* carries the coordinates of a single position as a sequence of numbers.

951 **A.1.8.3 Attribute: dimension**

952 The attribute *dimension* identifies the dimension of the coordinate space. This information is
953 derived through the association to SC_CRS. For framework orthoimagery, the value of
954 dimension is constrained to 2.

955 {origin.dimension = 2}

956 **A.1.8.4 Association role: coordinateReferenceSystem**

957 The association role *coordinateReferenceSystem* identifies the instance of SC_CRS to which the
958 DirectPosition is referenced.

959 **A.1.9 SC_CRS**

960 SC_CRS, as specified in ISO 19111 is an abstract class, meaning that it can only be instantiated
961 as an instance of one of its concrete subclasses. This part requires that coordinate reference
962 system be associated with either the North American Datum of 1983 (NAD83) or the datum
963 defined for the World Geodetic System of 1984 (WGS84). These two coordinate reference
964 systems are instances of the subclass SC_CoordinateReferenceSystem.

965 **A.1.10 SC_CoordinateReferenceSystem**

966 **A.1.10.1 Introduction**

967 The data type class SC_CoordinateReferenceSystem inherits two attributes from SC_CRS and
968 has four attributes defined for the class itself. Four of these attributes are optional; none of the
969 four is required by this part, so they are not documented in the text below.

970 **A.1.10.2 Attribute: kindCode**

971 The attribute *kindCode* is inherited from SC_CRS. Its data type is the enumeration
972 SC_KindCode, which includes two values. The value for any 2D horizontal coordinate reference
973 system is 1, generalCase.

974 **A.1.10.3 Attribute: CRSID**

975 The attribute *CRSID* contains an identifier for the coordinate reference system. Its data type is
976 RS_Identifier. RS_Identifier has one mandatory attribute, code; its value is of data type
977 CharacterString.

978

Table A.2 – Data dictionary for orthoimagery

Line	Name/Role Name	Definition	Obligation/ Condition	Maximum Occurrence	Data Type	Domain
1	Orthoimage	Set of data forming an orthorectified image of a portion of the Earth's surface			<<Feature>>	Lines 2-17
2	domainExtent	Spatial extent of the image	M	*	EX_Extent	Unrestricted
3	rangeType	Description of the types of values in the range of the coverage	M	1	RecordType	Unrestricted
4	interpolationType	Recommended method for interpolating values at points within grid cells	M	1	<<CodeList>> Coverage Core:: CV_InterpolationMethod	Unrestricted. Default is bilinear
5	commonPointRule	Rule to follow in interpolating a value at a point that falls on the boundary between two pixels	M	1	<<CodeList>> Segmented Curve:: CV_CommonPointRule	Unrestricted. Default is average
6	dimension	Dimension of the image grid	M	1	Integer	2
7	origin	Coordinates, in an external coordinate system, that map to grid coordinates 0, 0	M	1	<<DataType>> Elevation:: DirectPosition	Unrestricted
8	axisNames	Names of the axes of the image grid	M	1	Sequence<CharacterString>	"row", "column"
9	offsetVectors	Vectors that specify the orientation of the grid axes and the dimensions of the pixels in directions parallel to the axes	M	1	Sequence<Vector>	Unrestricted
10	extent	Limits of the set of pixels included in the image	M	1	<<DataType>> Quadrilateral Grid:: CV_GridEnvelope	Unrestricted
11	sequencingRule	Rule for assigning values to specific pixels	M	1	<<DataType>> Quadrilateral Grid:: CV_SequenceRule	Unrestricted
12	startSequence	Grid point associated with the first	M	1	<<DataType>> Quadrilateral Grid:: CV_StartSequence	Unrestricted

Annex C
(informative)
Additional information about control

1019 Currently, there are three methods used to acquire the necessary control; from existing map or
1020 digital orthoimagery, from a ground survey, or from a platform specific navigation direct
1021 georeferencing system composed of an Airborne Global Positioning System (AGPS) and Inertial
1022 Navigation System (INS).

1023 Control data in the form of survey ground control provides coordinates and elevations of known
1024 locations on the Earth's surface which are used in the orthorectification process to obtain the
1025 precise location and orientation of the raw image at the time it was acquired. This is
1026 accomplished through a process called aerotriangulation which derives the camera attitude and
1027 positions by performing a space resection using ground control, tie points, and camera model
1028 geometry. When completed, this process provides the location and orientation information of the
1029 all the imagery allowing the user to locate any on-the-ground positions to known projections,
1030 coordinates, and accuracy standards.

1031 Control derived from existing map or orthoimagery sources can also be used during the
1032 orthorectification process similarly to that of survey ground control. Control locations would
1033 consist of known horizontal and vertical values that, in turn, can be used in aerotriangulation
1034 process. For any given final orthoimage scale, control derived from a less accurate source is not
1035 recommended.

1036 Direct georeferencing currently incorporates both airborne AGPS and INS data and is the
1037 measurement of sensor position and orientation allowing for direct relationship between locations
1038 on the imagery to locations on the ground, without the need for additional ground information over
1039 the project area.

1040 Airborne GPS consists of a GPS unit on an aircraft that captures range measurements to
1041 satellites and uses triangulation techniques to compute the position of the receiver's antenna and
1042 relates that position to the sensor.

1043 Inertial Navigation System is composed of two components, one is the inertial measurement unit
1044 (IMU) comprised of a series of accelerometers and gyros that measure position, orientation, and
1045 velocity, and the second is the navigation processor of the INS which solves for the motion of the
1046 IMU. The two combined provide a navigation solution comprised of the platform's position,
1047 velocity, and orientation.

1048 When the data from the AGPS system is integrated with the INS data, the 3-dimensional and
1049 angular position of the aircraft sensor can be accurately estimated as the position of the AGPS
1050 complements that of the INS data providing location and orientation information helping to
1051 estimate and correct the errors of the imaging platform. The AGPS and INS data can then be
1052 used to help locate and orient the image in space during the orthorectification process.

1053 At times, digital orthoimagery may be created using direct georeferencing information without the
1054 need of any ground survey control. In other cases, this information is used to augment the
1055 aerotriangulation block adjustment solution.
