

How Good is Good Enough?

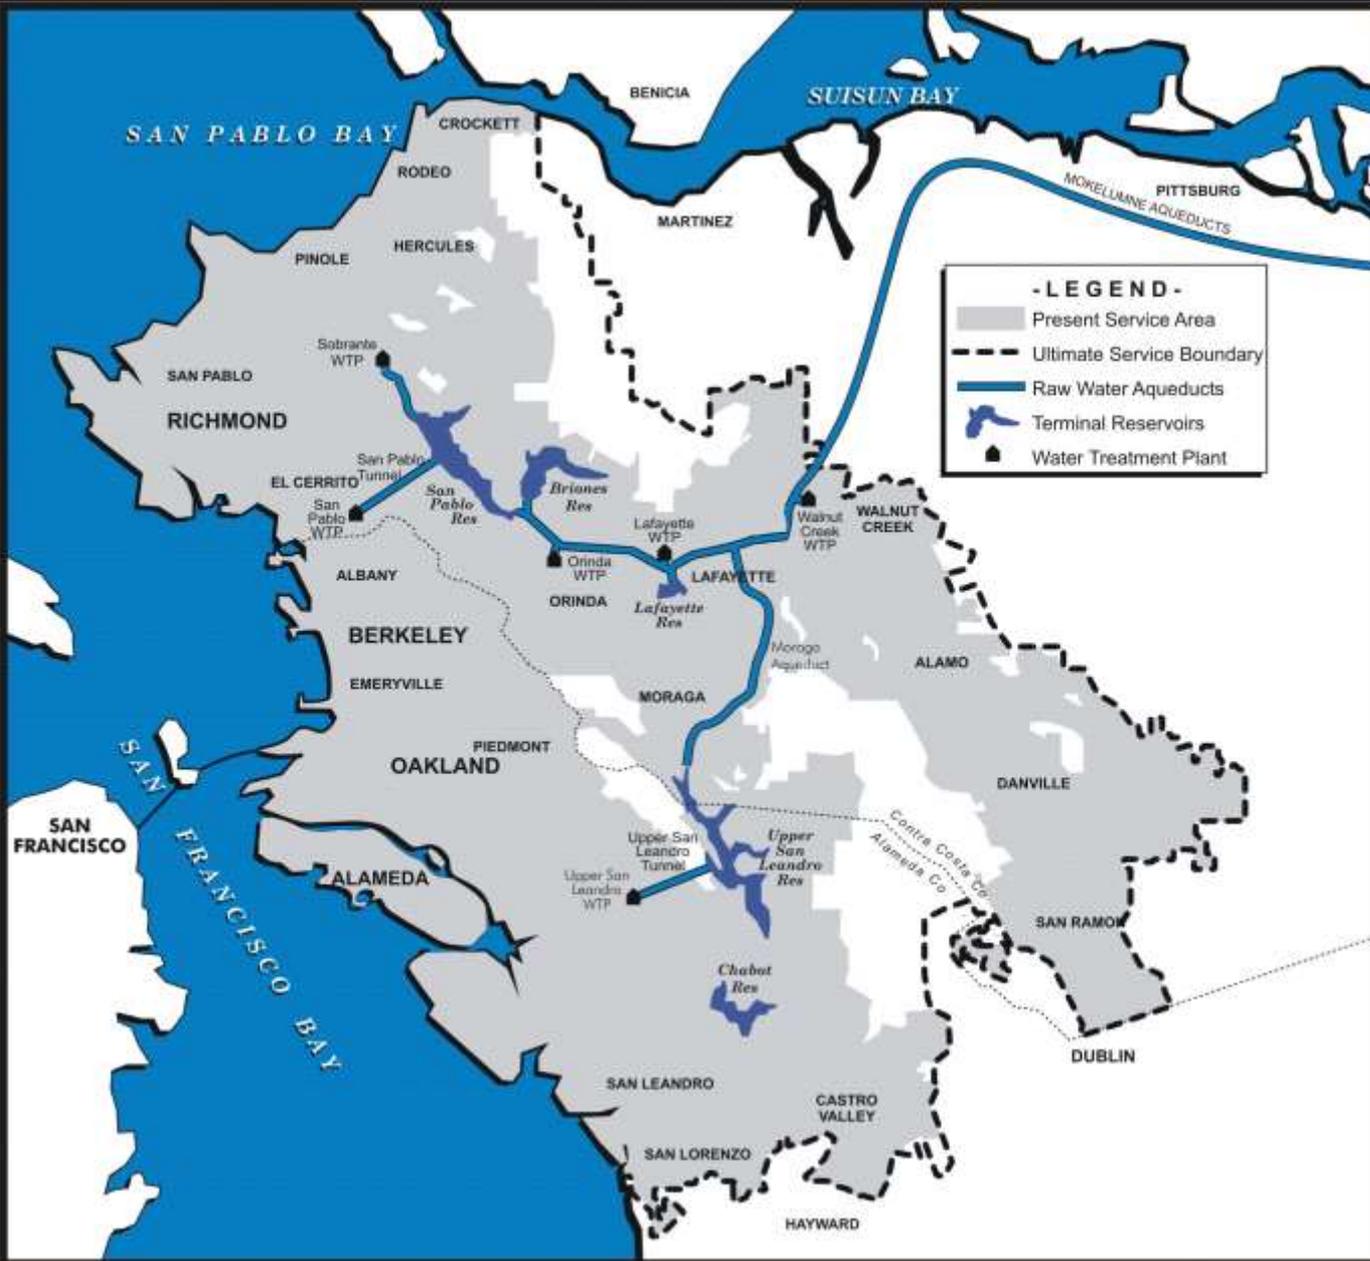

September 27, 2016
NGAC Meeting

This image shows a Hammer retro-azimuthal projection, in which azimuths to center are true. All world views sacrifice fidelity in one aspect to gain it in others.

Outline

1. EBMUD and its geospatial data
2. What's the problem?
3. Outline of a solution

EBMUD's Water System

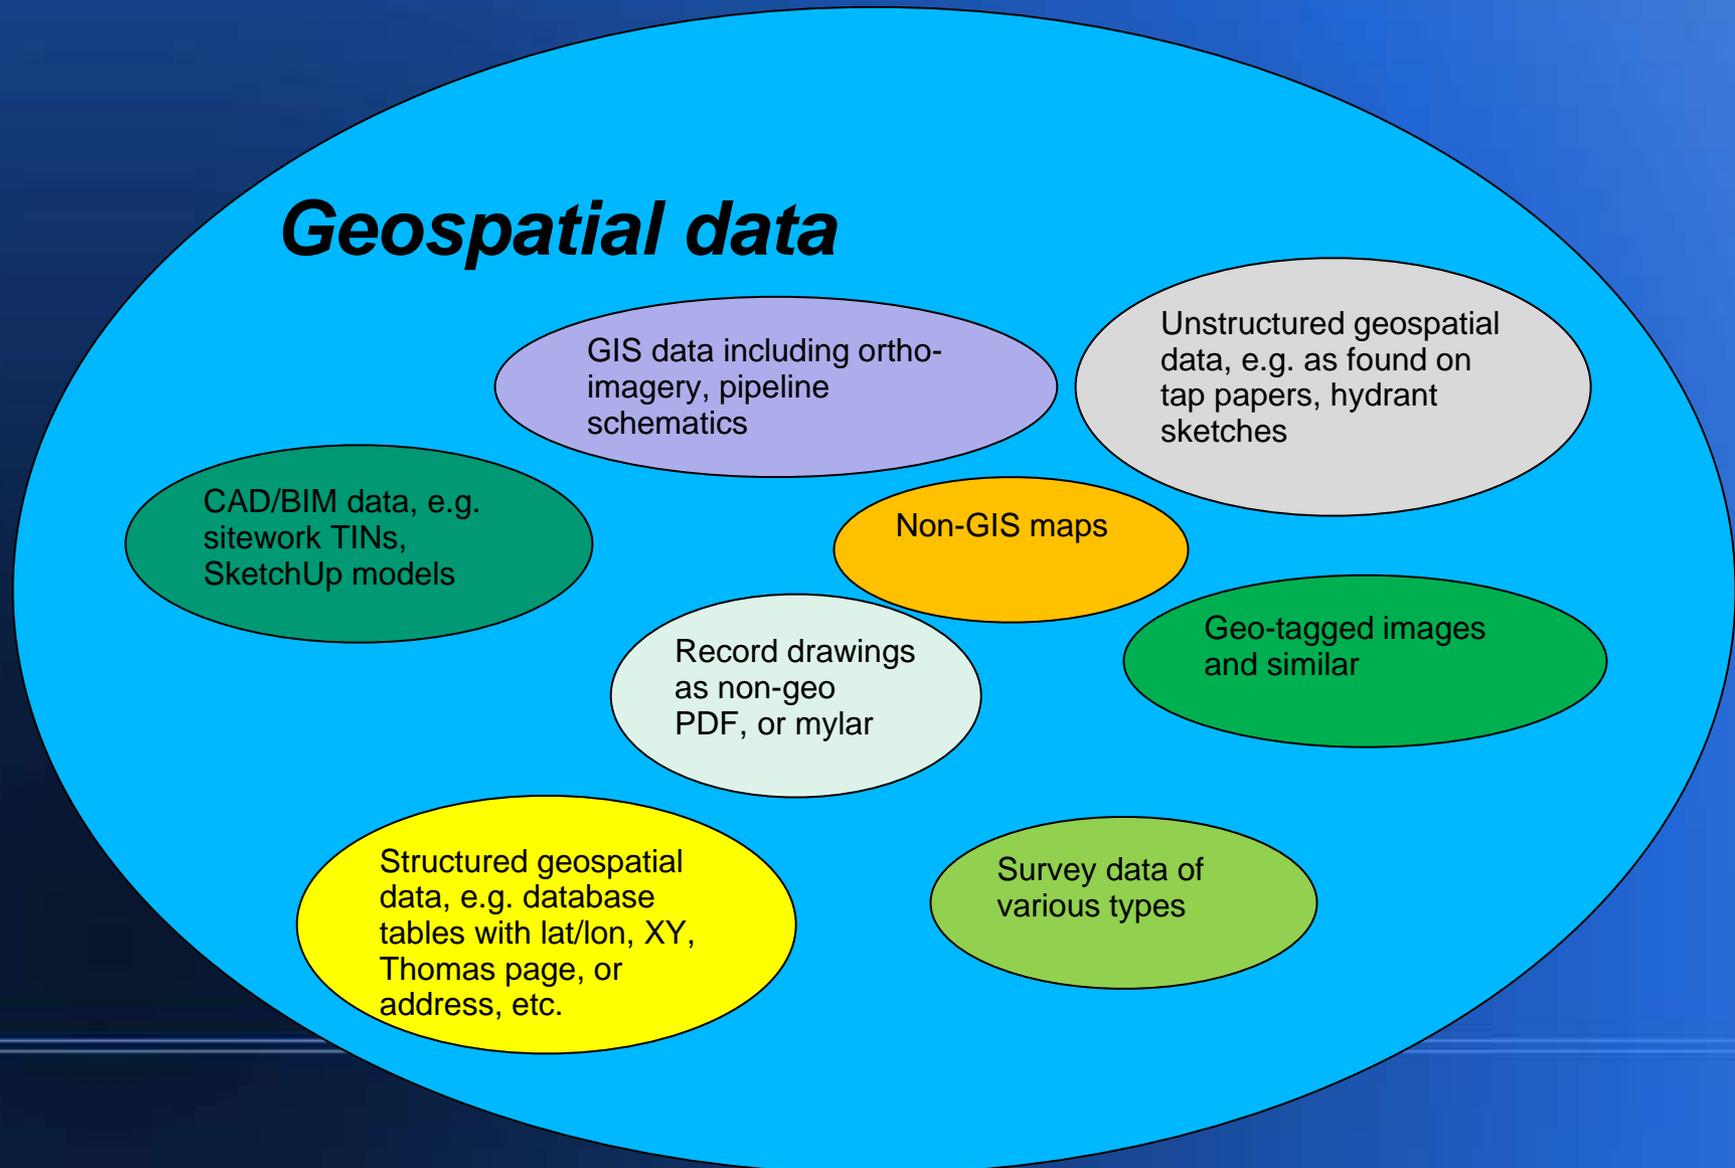

1,300,000 retail customers
400,000 services
6,600 km pipe
31 dams
5 treatment plants
126 pumping plants
165 reservoirs/tanks
122 pressure zones
Elevation: MSL-442 m

Geospatial data used by EBMUD

- Location and geometry of assets:
 - 4,300 miles of pipe
 - 400,000 meters
 - Hundreds of 1000's of appurtenances (services, valves, etc)
- Location of important events
 - Work orders
 - Leaks
 - Repairs
 - Investigations

A photograph of a 'TAP' report form from the City of Berkeley, dated 8/2/05. The form includes fields for 'TAP ID', 'TAP NO.', 'TAP DATE', and 'TAP TYPE'. It also features a 'REPORT' section with handwritten notes and a signature.

Record Drawing Creation

One of Our Geospatial Challenges

1. Existing GIS is schematic
2. Not able to properly support modern workflows:
 - 50,000 utility locates per year
 - 10,000 excavations per year
 - Increasingly congested sub-surface

Existing GIS still shows its 1920's roots since 1928

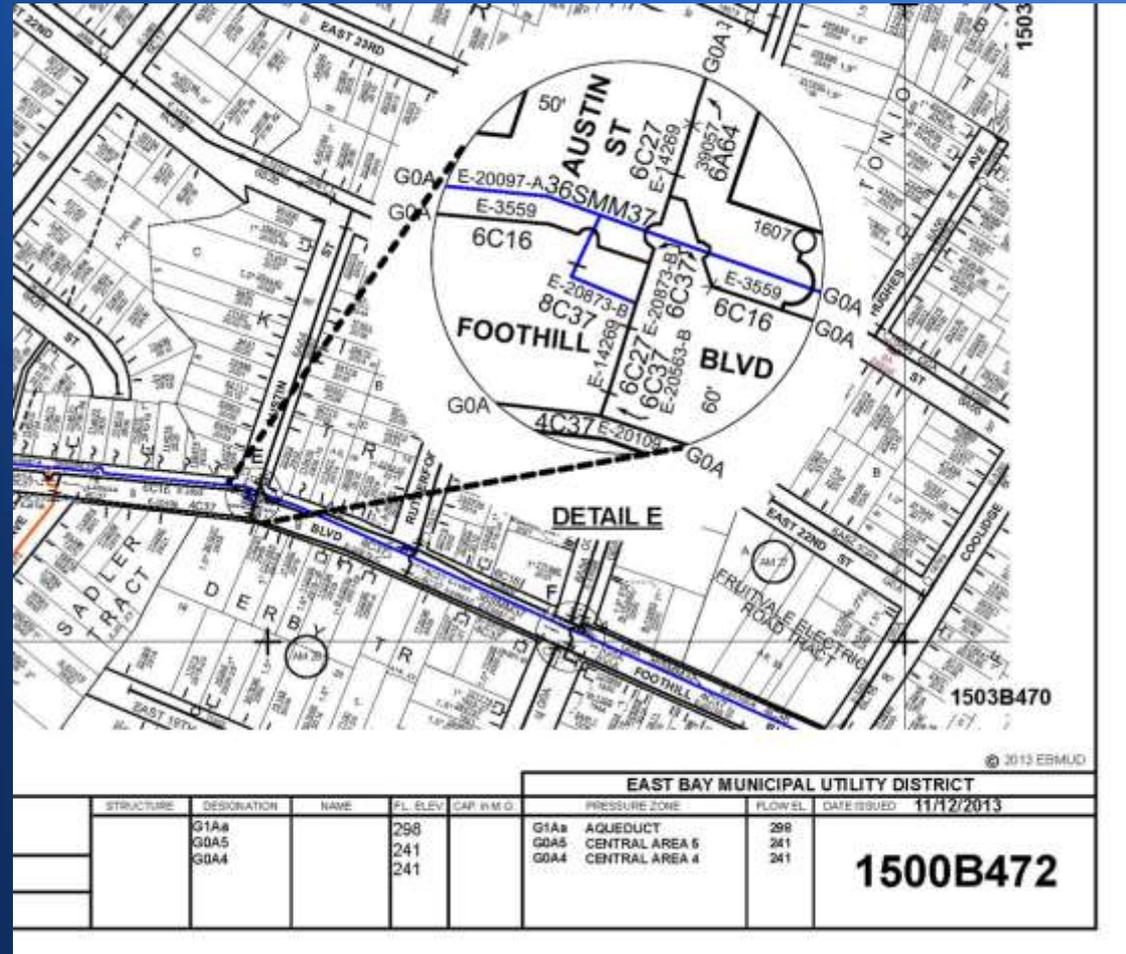

Traditional Emphasis on “Cartographic Clarity” over Geographic Fidelity

Rationale:

- Maps of today are schematic because if shown geographically true, parallel pipes will end up nearly atop one another
- Many pipe intersections are very complex

Downsides to schematic approach:

- Pipes may be shown far from true location
- Inter-utility conflict detection is impossible
- Requires extra labor
- Not good for location-aware apps

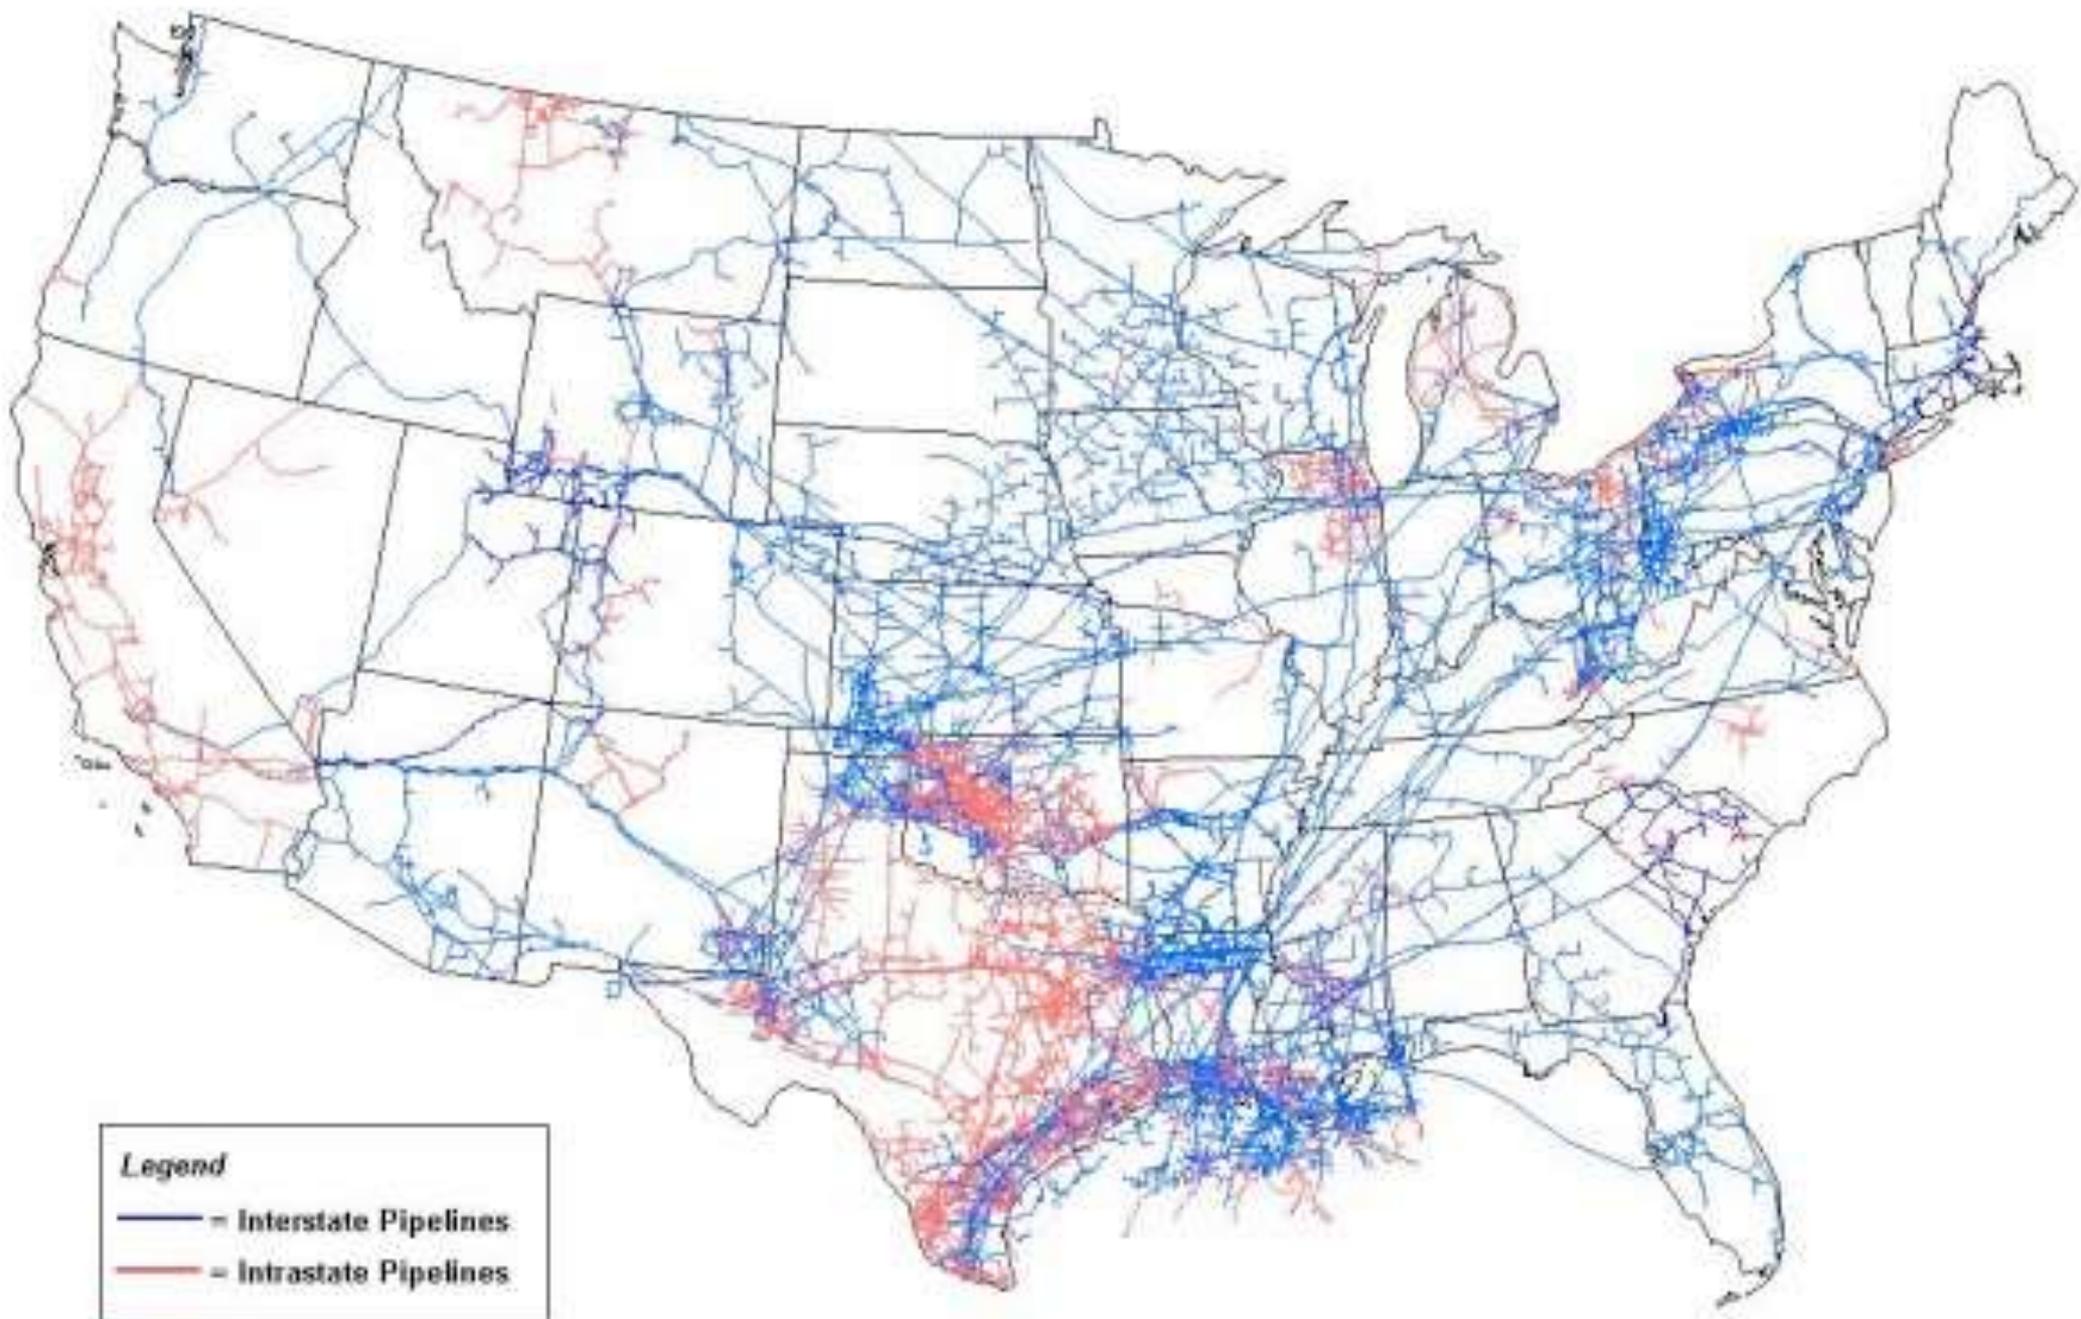

Locating Valves and Pipes is Hugely Time-Consuming

How Exactly Should We Transition to Geographic Accuracy?

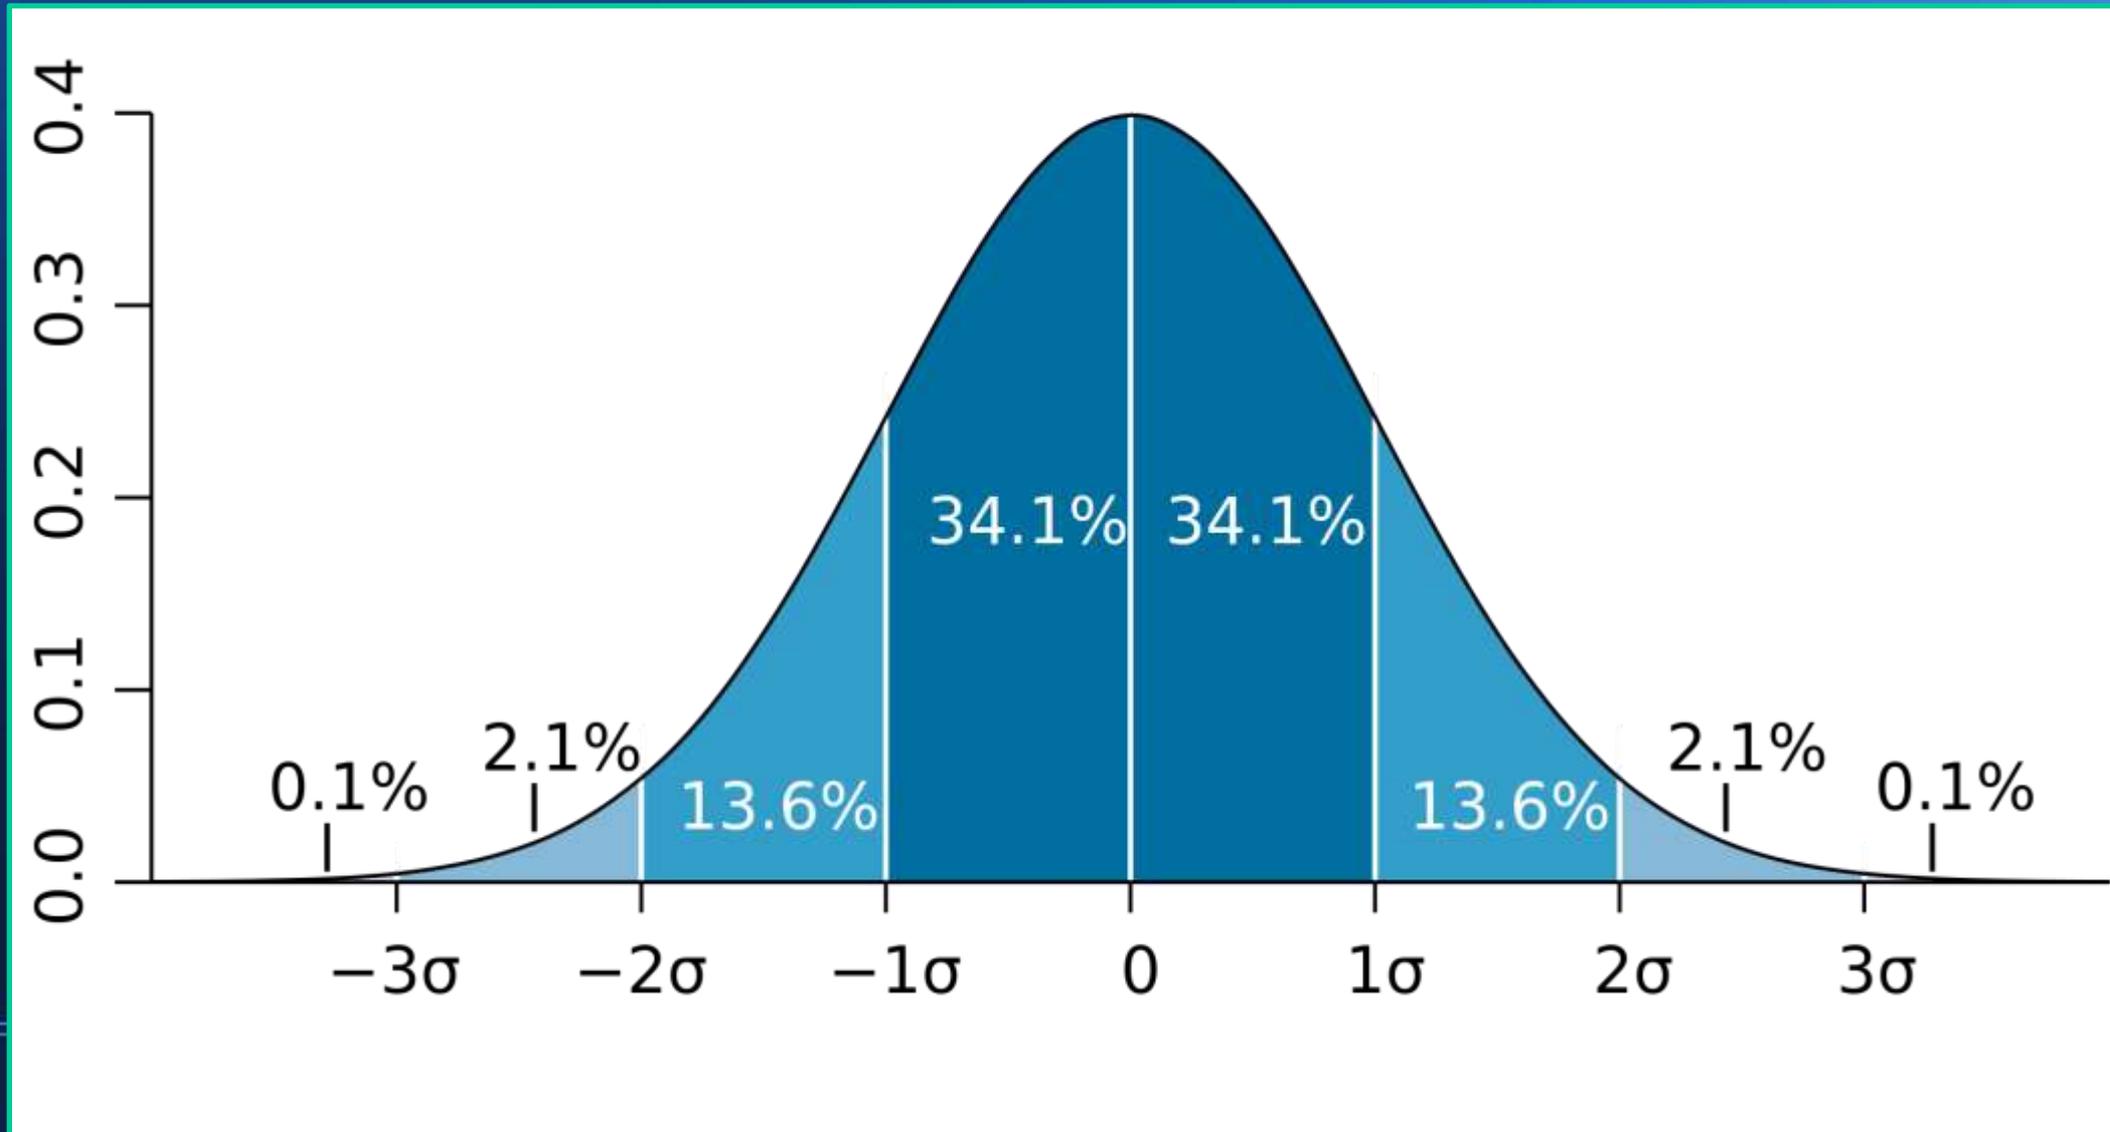

Modern GPS systems can provide:

- 1" accuracy XY in the field
- Text annotations and photos linked to the data
- No post-processing required

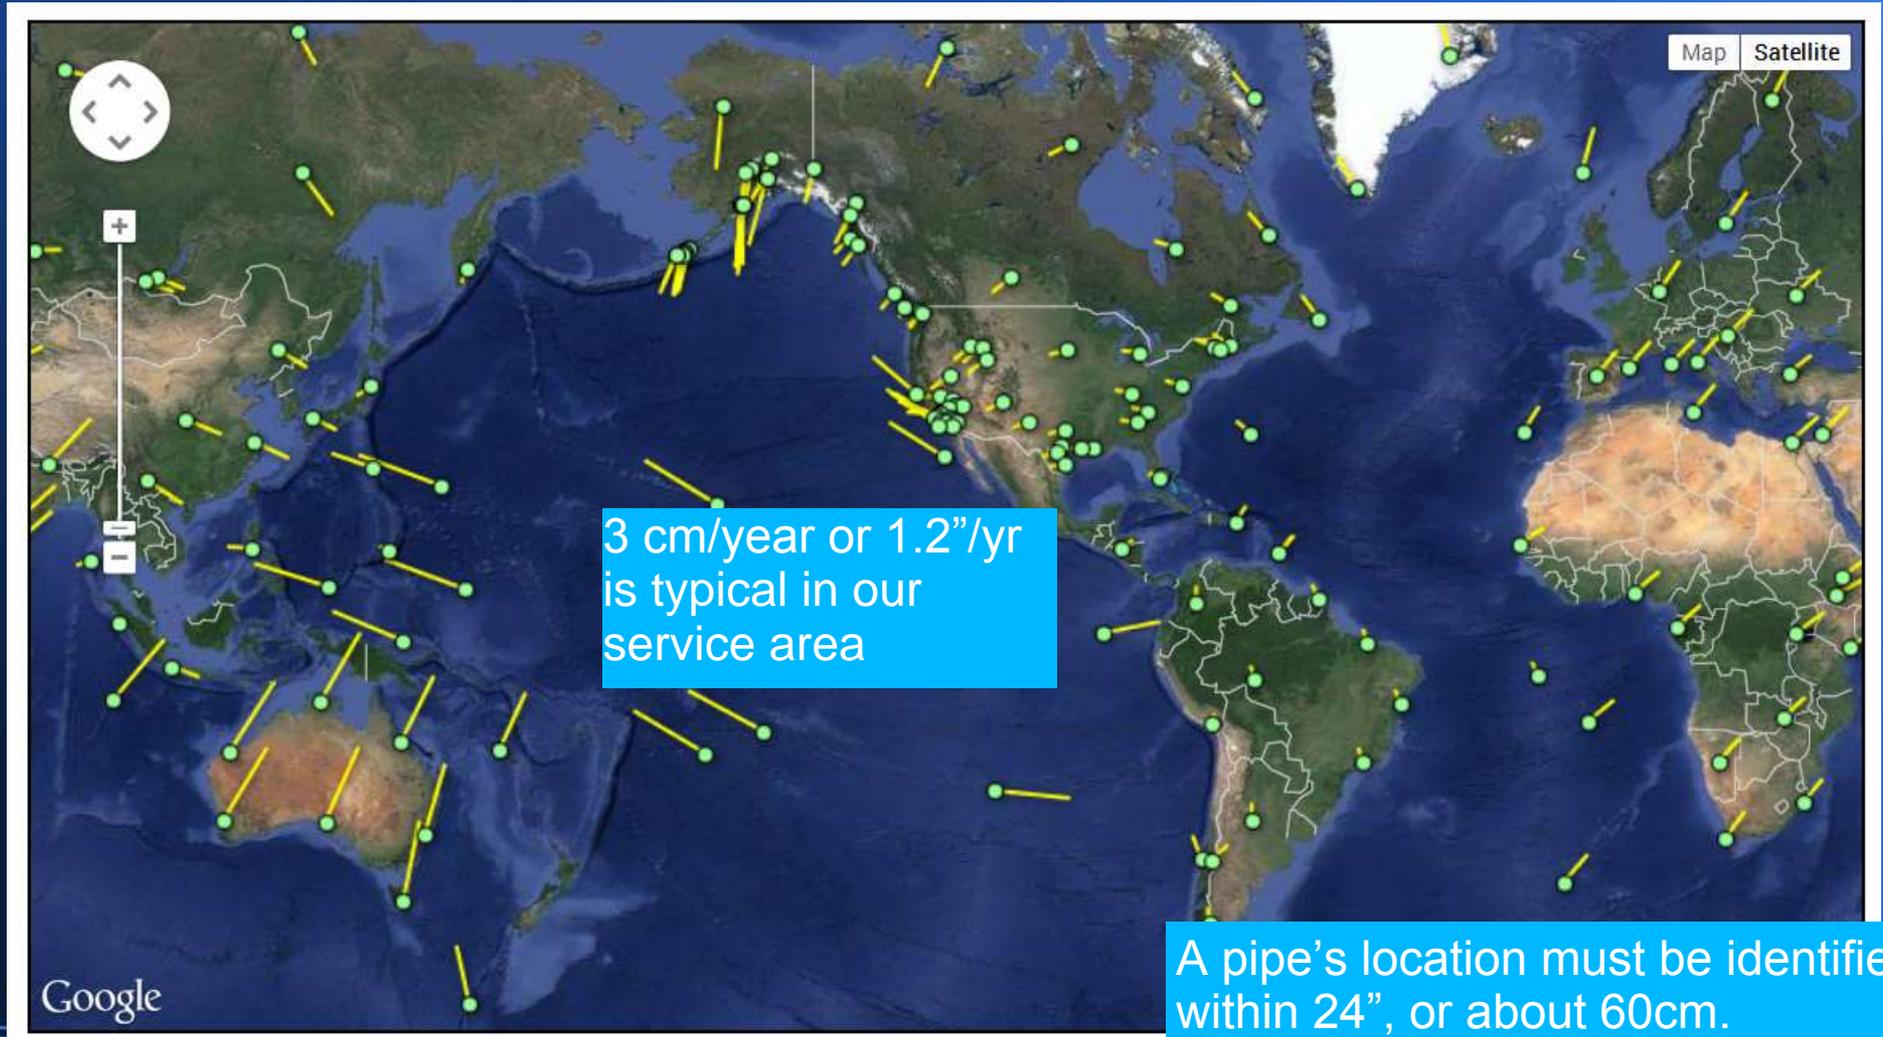

Versus smart phones:

- Data are super cheap and easy to grab
- But accuracy is often 2' or worse RMS

How Good is Good Enough?

Hold Your Answer: Tectonic Drift is not negligible

Summary

1. We need to reliably be within 2'
2. That means RMS error of about 8"
3. We need to allow for various sources of error including initial capture, tectonic drift, datum conversions, mapping error
4. Capture accuracy of 3" or so is not unreasonable
5. And we need to get our datums, projections, etc. right — this means good metadata & user training
